

European eel (*Anguilla anguilla*) throughout its natural range

ICES advice on fishing opportunities

ICES advises that when the precautionary approach is applied, there should be zero catches in all habitats in 2022. This applies to both recreational and commercial catches and includes catches of glass eels for restocking and aquaculture.

All other anthropogenic mortalities should be minimized and eliminated where possible.

Stock development over time

The status of European eel remains critical.

Indices of both glass and yellow eel recruitment strongly declined from 1980 to 2011. Index values correspond to the recruitment as a percentage of the 1960–1979 geometric mean. Glass eel recruitment in the “North Sea” index area, was 0.6% in 2021 (provisional) and 0.9% in 2020 (final). In the “Elsewhere Europe” index series it was 5.4% in 2021 (provisional) and 7.1% in 2020 (final), based on the available dataserries. For the yellow eel dataserries, recruitment for 2020 was 16% (final) of the 1960–1979 geometric mean; the 2021 data collection for yellow eel is ongoing. Time-series from 1980 to 2021 show that glass eel recruitment remains at a very low level.

ICES cannot assess the exploitation status relative to the maximum sustainable yield (MSY) and precautionary approach (PA) reference points, because the reference points are undefined. The 1960–1979 recruitment is considered as a likely limit reference point (R_{lim}). Given that the current Recruitment estimate has been below R_{lim} for many years, it is assumed that current biomass is below a likely B_{lim} . Therefore, while stock-size reference points are also undefined, it is considered likely that the stock size is well below potential biological reference points.

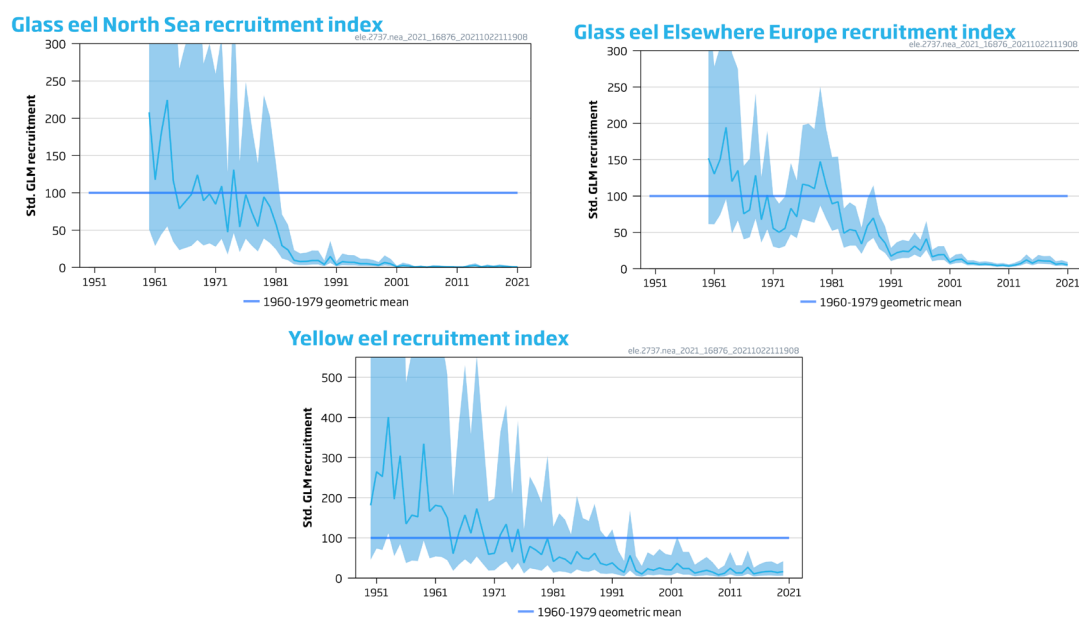

Figure 1 European eel. Indices, geometric mean of estimated (generalized linear model; GLM) glass eel recruitment for the continental “North Sea” (top left panel) and “Elsewhere Europe” (top right panel) series. The GLM was fitted to 56 time-series comprising either pure glass eel or a mixture of glass and yellow eels (26 “North Sea” and 30 “Elsewhere Europe”). The GLM was scaled in percentage to the 1960–1979 geometric mean. The “North Sea” series are from Norway, Sweden, Germany, Denmark, the Netherlands, and Belgium; the “Elsewhere” series are from UK, Ireland, France, Spain, Portugal, and Italy. In the Baltic area, recruitment occurs at the yellow eel stage only, and series are thus not included in the glass eel recruitment index. Bottom panel: estimated (GLM) yellow eel recruitment trends for Europe. The GLM was fitted to 21 yellow eel time-series and scaled in percentage to the 1960–1979 geometric mean. The series are from Denmark, Germany, Ireland, Sweden, and UK.

Catch scenarios

ICES is not in a position to provide catch scenarios in the absence of accurate catch information.

Basis of the advice

Table 1 European eel. The basis of the advice.

Advice basis	Precautionary approach
Management plan	<p>A management framework for eel within the EU was established in 2007 by Council Regulation (EC) No. 1100/2007 (EU, 2007) and the General Fisheries Commission for the Mediterranean (GFCM) adopted Recommendation GFCM/42/2018/1 (GFCM, 2018), establishing management measures for European eel (<i>Anguilla anguilla</i>) in the Mediterranean Sea.</p> <p>These management plans have not been evaluated by ICES for their conformity with the precautionary approach and, for this reason, have not been used as the basis for the advice.</p>

Quality of the assessment

The advice is based on two glass eel recruitment indices and a yellow eel recruitment index, each comprising multiple time-series. The indices are based on data from fisheries and scientific surveys, forming the longest and most reliable time-series that constitute an index of abundance. The quality of the underlying recruitment data and the number of time-series reported yearly is variable. Fifty-six glass eel and 21 yellow eel series were used in the analysis in 2021. The current advice is based on the fact that the recruitment indices used by ICES are well below the 1960–1979 geometric mean. The decline in yellow eel recruitment becomes more pronounced when data from the 1950s are used rather than the currently used baseline. However, because so few robust pre-1960s time-series are available, the baseline was set to the geometric mean of the 1960–1979 as in previous advice.

In 2021, seven new recruitment series were added to the recruitment trend analyses because these series now reached the agreed limit value of at least ten years of observations. A specific analysis of the influence of including new series over time has been conducted this year, which found that this inclusion confirms the recruitment trend.

Total landings and effort data are incomplete. In addition, a great heterogeneity is present among the time-series of landings owing to inconsistencies in reporting by, and between, countries. Changes in eel management practices have also affected commercial and non-commercial/recreational fisheries and the reporting of these fisheries.

Data deficiencies in reports on recreational fisheries are described by ICES (2016a). Though there has been evidence of improvements since then, landings in recreational fisheries remain largely unquantified. Estimates from countries, where they are available, show that landings in recreational fisheries can be of the same order of magnitude as in commercial fisheries (except for glass eels).

An eel data call, issued for the first time in 2017, substantially improved the coverage and completeness of the data being reported to ICES. Subsequent annual calls were issued, the national stock indicators and associated data every third year, as reported to the EU in the progress reports. The most recent call was issued in 2021 (ICES, 2021a). Data on eel, fisheries, and other anthropogenic impacts across the whole stock, however, remain incomplete. There is no single international legislative requirement to collect and provide data that cover the entire stock area.

Issues relevant for the advice

The current advice is for zero catches of eel at all life stages in all habitats. The following implications should be considered:

- *Other anthropogenic mortalities*

The non-fishing anthropogenic mortality factors are substantial (ICES 2019a, 2020, 2021b) and can be grouped into those that result from the following: (a) hydropower, pumping stations, and other water intakes; (b) habitat loss or degradation; (c) pollution, diseases, and parasites; and (d) other management actions that may affect levels of predation (e.g. conservation vs. control of predators). Climate change may have further effects, but these are not understood.

Environmental impacts in marine, transitional, and freshwaters all contribute to the anthropogenic stresses on eels, their mortality, and their reproductive success. The implementation of environmental legislation (e.g. the EU Water Framework [WFD] and the Marine Strategy Framework directives [MSFD]) aim to improve the continental environment and could have a positive effect on the reproductive potential of silver eel.

At present, ICES is not able to quantify the level and the relative impact of non-fisheries anthropogenic factors on the reproductive capacity of the stock. However, given the state of the stock, ICES advises that all non-fisheries anthropogenic impacts (e.g. caused by hydropower, pumping stations, and pollution) that decrease production and escapement of silver eels should be reduced to, or kept as close as possible to, zero in 2022.

- *Restocking*

ICES notes that the restocking of eels (the practice of adding eels to a waterbody from another source) is considered a “conservation measure” in the EU regulation and in many eel management plans for achieving the 40% escapement target on all EMUs (Eel Management Unit). Restocking is reliant on a glass eel fishery catch, which is in contradiction with the current advice.

The net benefit of restocking of eels to reproductive potential of the stock is unknown. It requires information on e.g. carrying capacity estimates of glass eel source estuaries, detailed mortality estimates at each step of the restocking process, and performance estimates of stocked vs. non-stocked eels. ICES advises that given the above mentioned uncertainties and potential harmful effects (ICES 2016b), and following the precautionary approach, any catch for restocking should not be allowed.

- *Aquaculture*

Since cultured eels are always wild caught and either permanently removed from the stock (for consumption) or used for restocking (and hence not for conservational purposes following the definition below), ICES consequently advises that any catch for aquaculture purposes should not be allowed.

- *Conservation measures:*

ICES acknowledges that catches for the purpose of subsequent release to improve survival may be part of conservation measures, e.g. where dams exist and prevent downstream or upstream migration of silver and glass eel, transfer across barriers within the same waterbody could be considered, assuming that any associated mortality is less than that in the absence of such measures. Furthermore, upstream migration should only be applied if the future escapement of silver eels is ensured. In such conditions, the current advice does not apply to these catches.

- *Potential loss of fisheries-dependent time-series:*

Many fishery-based time-series are utilized to assess temporal trends in recruitment and escapement. Changes to these time-series (e.g. through new fishery regulations or changes to habitat) may introduce biases in the time-series and compromise their use in the analyses. Sensitivity analyses showed that the current assessment was not sensitive to changes in fishery-based time-series; yet, losing these time-series would increase the noise in the outcome (i.e. standard error around the trend increases). This means that continuation of existing and the implementation of new fishery-independent time-series is recommended, especially since all time-series need to run for at least ten years of observations before they can be incorporated into the recruitment index.

Illegal, unreported, and unregulated (IUU) fishing is known to occur. However, customs seizures indicate that the illegal export of glass eel could be substantial, potentially exceeding the legal market. Few countries reported the level of misreporting and illegal fisheries to ICES, EIFAAC, and GFCM (i.e. the seizure of illegal nets as well as the illegal trade of glass eels from countries both inside and outside the EU).

The European eel (*Anguilla anguilla*) has been listed in CITES Appendix II and in the EU implementation of CITES rules (Annex B to Council Regulation (EC) No 338/97; EU, 1996) since 13 March 2009. Since 2010, import and export of eel from the EU has been prohibited. Some non-EU states within the range of European eel allow export of European eel, mostly to the Far East.

Reference points

No reference points are formally defined for this stock. For the time being, the 1960–1979 recruitment is considered as a likely limit reference point (R_{lim} ; ICES, 2021c).

Basis of the assessment

Summary of the assessment

Table 8 European eel. Recruitment indices: geometric means of estimated (GLM) recruitment for glass eel in the continental “North Sea” and “Elsewhere Europe”, and recruitment of yellow eel in Europe. The glass eel GLM (predicting recruitment as a function of area, year, and site) was fitted to 56 time-series, comprising either pure glass eel or a mixture of glass eels and yellow eels and scaled to the 1960–1979 geometric mean so that values correspond to the recruitment as a percentage of the 1960–1979 geometric mean. The yellow eel GLM (predicting recruitment as a function of year and site) was fitted to 16 yellow eel time-series and scaled to the 1960–1979 geometric mean so that values correspond to the recruitment as a percentage of the 1960–1979 geometric mean. These indices are updated on an annual basis and, as they are presented in relative terms, may change the historical values.

Year	Elsewhere Europe index (%)	North Sea Index (%)	Yellow eel Europe index (%)
